

TITLE

FRUCTAN BIOSYNTHETIC ENZYMES

This application claims the benefit of U.S. Provisional Application No. 60/244,273, filed October 30, 2000, and U.S. Provisional Application No. 60/269,543, filed February 16, 2001. The entire contents of these two applications are herein incorporated by reference.

FIELD OF THE INVENTION

This invention is in the field of plant molecular biology. More specifically, this invention pertains to nucleic acid fragments encoding fructosyltransferases in plants and seeds.

BACKGROUND OF THE INVENTION

Fructans are linear or branched polymers of repeating fructose residues with usually one terminal glucose unit. The number of residues contained in an individual polymer, also known as the degree of polymerization (DP), varies greatly depending on the source from which the polymer is isolated. Several bacteria can produce fructans with a DP 5000 or greater, while low DP fructans (DP 3 to 200) are found in over 40,000 plant species.

Based on their structure, several types of fructans can be identified in higher plants. The most characterized plant fructan is inulin. Inulin contains linear $\beta(2-1)$ -linked fructosyl residues and commonly occurs in the *Asterales* such as Jerusalem artichoke (*Helianthus tuberosus*), sunflower (*Helianthus* sp.), Belgian endive (*Cichorium intybus*) and artichoke (*Cynara scolymus*). Inulin synthesis is initiated by sucrose:sucrose 1-fructosyltransferase (1-SST; EC 2.4.1.99) which catalyses the conversion of sucrose into isokestose (also named 1-kestose) and glucose. Additional fructosyl units are added onto isokestose, by the action of a fructan:fructan 1-fructosyltransferase (1-FFT, EC 2.4.1.100) resulting in a $\beta(2-1)$ -linked fructose oligomer.

A second type of fructan is called levan and consists of linear $\beta(2-6)$ linked fructosyl residues. Grasses such as *Dactylis glomerata* and *Phleum pratense* contain levans with a DP up to 200. Levans are synthesized by a sucrose:fructan 6-fructosyltransferase (6-SFT; EC 2.4.1.10) that uses sucrose as a fructosyl donor and acceptor to produce 6-kestose. Polymerization of 6-kestose is believed to be catalyzed by 6-SFT as well, using sucrose as the fructosyl donor.

A third type of fructan, graminan (also called mixed-levan), is found in many *Poales* such as barley and wheat. These plants use an SST to produce iso-kestose from sucrose, and 6-SFT to further polymerize isokestose, resulting in a fructan containing both the $\beta(2-1)$ and the $\beta(2-6)$ linked fructosyl residues.

The fourth type of fructan is often referred to as the neo-kestose series of fructans. The neo-kestose series have fructosyl residues on the carbon 1 and 6 of glucose producing a polymer with fructosyl residues on either end of the sucrose molecule. The inulin-neoseries found in *Liliales* such as onion (*Allium cepa*), leek (*Allium porrum*), and asparagus (*Asparagus officinales*) contain mainly a $\beta(2-1)$ -linked fructose polymer linked to carbon 1 and 6 of glucose, while the levan-neoseries contain mainly a $\beta(2-6)$ -linked fructose polymer linked to carbon 1 and 6 of glucose. Neoseries fructans are believed to be synthesized by the concerted action of 1-SST (producing isokestose) and 6G-FFT, a specific fructan:fructan 6G-fructosyltransferase that polymerizes fructosyl units onto carbon 6 of glucose.

Industrial applications of fructans are very diverse and range from medical, food, and feed applications, as well as the use of fructans as a raw material for the production of industrial polymers and high-fructose syrup. Regardless of size, fructose polymers are not metabolized by humans and animals. Fructans can enhance animal health and performance by being selectively fermented by beneficial organisms such as *Bifidobacterium* in the large intestine of animals, at the expense of pathogenic organisms such as *E. coli* and *Salmonella*, leading to altered fatty acid profiles, increased nutrient absorption, and decreased levels of blood cholesterol. Also, fructans have a sweet taste and are increasingly used as low-calorie sweeteners and as functional food ingredients.

Accordingly, there is a great deal of interest in understanding fructan biosynthetic pathways. With the isolation of nucleic acid fragments encoding various enzymes involved in the pathway, it may be possible to engineer transgenic plants to produce desired levels of different types of useful and novel fructans.

SUMMARY OF THE INVENTION

The present invention concerns an isolated polynucleotide comprising: (a) a first nucleotide sequence encoding a first polypeptide comprising at least 58 amino acids, wherein the amino acid sequence of the first polypeptide and the amino acid sequence of SEQ ID NO:12 have at least 90% or 95% identity based on the Clustal alignment method, (b) a second nucleotide sequence encoding a second polypeptide comprising at least 140 amino acids, wherein the amino acid sequence of the second polypeptide and the amino acid sequence of SEQ ID NO:6 have at least 90% or 95% identity based on the Clustal alignment method, (c) a third nucleotide sequence encoding a third polypeptide comprising at least 471 amino acids, wherein the amino acid sequence of the third polypeptide and the amino acid sequence of SEQ ID NO:10 have at least 95% identity based on the Clustal alignment method, (d) a fourth nucleotide sequence encoding a fourth polypeptide

comprising at least 495 amino acids, wherein the amino acid sequence of the fourth polypeptide and the amino acid sequence of SEQ ID NO:8 have at least 95% identity based on the Clustal alignment method, (e) a fifth nucleotide sequence encoding a fifth polypeptide comprising at least 600 amino acids, wherein the amino acid sequence of the fifth polypeptide and the amino acid sequence of SEQ ID NO:2 have at least 85%, 90%, or 95% identity based on the Clustal alignment method, (f) a sixth nucleotide sequence encoding a sixth polypeptide comprising at least 600 amino acids, wherein the amino acid sequence of the sixth polypeptide and the amino acid sequence of SEQ ID NO:4 or SEQ ID NO:14 have at least 90% or 95% identity based on the Clustal alignment method, (g) a seventh nucleotide sequence encoding a seventh polypeptide comprising at least 630 amino acids, wherein the amino acid sequence of the seventh polypeptide and the amino acid sequence of SEQ ID NO:16 have at least 97% identity based on the Clustal alignment method, or (h) the complement of the first, second, third, fourth, fifth, sixth, or seventh nucleotide sequence, wherein the complement and the first, second, third, fourth, fifth, sixth, or seventh nucleotide sequence contain the same number of nucleotides and are 100% complementary.

In a second embodiment, the first polypeptide preferably comprises the amino acid sequence of SEQ ID NO:12, the second polypeptide preferably comprises the amino acid sequence of SEQ ID NO:6, the third polypeptide preferably comprises the amino acid sequence of SEQ ID NO:10, the fourth polypeptide preferably comprises the amino acid sequence of SEQ ID NO:8, the fifth polypeptide preferably comprises the amino acid sequence of SEQ ID NO:2, the sixth polypeptide preferably comprises the amino acid sequence of SEQ ID NO:4 or SEQ ID NO:14, and the seventh polypeptide preferably comprises the amino acid sequence of SEQ ID NO:16.

In a third embodiment, the first nucleotide sequence preferably comprises the nucleotide sequence of SEQ ID NO:11, the second nucleotide sequence preferably comprises the nucleotide sequence of SEQ ID NO:5, the third nucleotide sequence preferably comprises the nucleotide sequence of SEQ ID NO:9, the fourth nucleotide sequence preferably comprises the nucleotide sequence of SEQ ID NO:7, the fifth nucleotide sequence preferably comprises the nucleotide sequence of SEQ ID NO:1, the sixth nucleotide sequence preferably comprises the nucleotide sequence of SEQ ID NO:3 or SEQ ID NO:13, and the seventh nucleotide sequence preferably comprises the nucleotide sequence of SEQ ID NO:15.

In a fourth embodiment, the first, second, third, fourth, fifth, sixth, and seventh polypeptides preferably are fructosyltransferases.

In a fifth embodiment, the first, third and fourth polypeptides preferably are 6-SFT, the second and fifth polypeptides preferably are 1-FFT, the sixth polypeptide preferably is 1-FFT or 1-SST, and the seventh polypeptide preferably is 1-SST.

In a sixth embodiment, this invention relates to a vector comprising the polynucleotide of the present invention, or to a recombinant DNA construct comprising the polynucleotide of the present invention operably linked to at least one regulatory sequence. The invention includes a cell, a plant, or a seed comprising the recombinant DNA construct of the present invention. The cell may be a eukaryotic cell such as a plant cell, or a prokaryotic cell such as a bacterial cell.

In a seventh embodiment, the invention relates to a virus, preferably a baculovirus, comprising an isolated polynucleotide of the present invention or a recombinant DNA construct of the present invention.

In an eighth embodiment, the invention relates to a method of transforming a cell by introducing into the cell a nucleic acid comprising a polynucleotide of the present invention. The invention also concerns a method for producing a transgenic plant comprising transforming a plant cell with any of the isolated polynucleotides of the present invention and regenerating a plant from the transformed plant cell, the transgenic plant produced by this method, and the seed obtained from this transgenic plant.

In a ninth embodiment, the present invention relates to (a) a method for producing a polynucleotide fragment comprising selecting a nucleotide sequence comprised by any of the polynucleotides of the present invention, wherein the selected nucleotide sequence contains at least 30, 40, or 60 nucleotides, and synthesizing a polynucleotide fragment containing the selected nucleotide sequence, and (b) the polynucleotide fragment produced by this method.

In a tenth embodiment, the present invention relates to an isolated polynucleotide fragment comprising a nucleotide sequence comprised by any of the polynucleotides of the present invention, wherein the nucleotide sequence contains at least 30, 40, or 60 nucleotides, and a cell, a plant, and a seed comprising the isolated polynucleotide.

In an eleventh embodiment, the present invention concerns an isolated polypeptide comprising: (a) a first amino acid sequence comprising at least 58 amino acids, wherein the first amino acid sequence and the amino acid sequence of SEQ ID NO:12 have at least 90% or 95% identity based on the Clustal alignment method, (b) a second amino acid sequence comprising at least 140 amino acids, wherein the second amino acid sequence and the amino acid sequence of SEQ ID NO:6 have at least 90% or 95% identity based on the Clustal

alignment method, (c) a third amino acid sequence encoding comprising at least 471 amino acids, wherein the third amino acid sequence and the amino acid sequence of SEQ ID NO:10 have at least 95% identity based on the Clustal alignment method, (d) a fourth amino acid sequence comprising at least 495 amino acids, wherein the fourth amino acid sequence and the amino acid sequence of SEQ ID NO:8 have at least 95% identity based on the Clustal alignment method, (e) a fifth amino acid sequence comprising at least 600 amino acids, wherein the fifth amino acid sequence and the amino acid sequence of SEQ ID NO:2 have at least 85%, 90%, or 95% identity based on the Clustal alignment method, (f) a sixth amino acid sequence comprising at least 600 amino acids, wherein the sixth amino acid sequence and the amino acid sequence of SEQ ID NO:4 or SEQ ID NO:14 have at least 90% or 95% identity based on the Clustal alignment method, or (g) a seventh amino acid sequence comprising at least 630 amino acids, wherein the seventh amino acid sequence and the amino acid sequence of SEQ ID NO:16 have at least 97% identity based on the Clustal alignment method. The first amino acid sequence preferably comprises the amino acid sequence of SEQ ID NO:12, the second amino acid sequence preferably comprises the amino acid sequence of SEQ ID NO:6, the third amino acid sequence preferably comprises the amino acid sequence of SEQ ID NO:10, the fourth amino acid sequence preferably comprises the amino acid sequence of SEQ ID NO:8, the fifth amino acid sequence preferably comprises the amino acid sequence of SEQ ID NO:2, the sixth amino acid sequence preferably comprises the amino acid sequence of SEQ ID NO:4 or SEQ ID NO:14, and the seventh amino acid sequence preferably comprises the amino acid sequence of SEQ ID NO:16. The polypeptide preferably is a fructosyltransferase. The first, third and fourth amino acid sequences preferably are 6-SFT, the second and fifth amino acid sequences preferably are 1-FFT, the sixth amino acid sequence preferably is 1-FFT or 1-SST, and the seventh amino acid sequence preferably is 1-SST.

In a twelfth embodiment, the invention concerns a method for isolating a polypeptide encoded by the polynucleotide of the present invention comprising isolating the polypeptide from a cell containing a recombinant DNA construct comprising the polynucleotide operably linked to a regulatory sequence.

In a thirteenth embodiment, the invention relates to a method of selecting an isolated polynucleotide that affects the level of expression of a fructan biosynthetic enzyme (fructosyltransferase) polypeptide or enzyme activity in a host cell, preferably a plant cell, the method comprising the steps of: (a) constructing an isolated polynucleotide of the present invention or an isolated recombinant DNA

construct of the present invention; (b) introducing the isolated polynucleotide or the isolated recombinant DNA construct into a host cell; (c) measuring the level of the fructan biosynthetic enzyme (fructosyltransferase) polypeptide or enzyme activity in the host cell containing the isolated polynucleotide or the isolated recombinant DNA construct; and (d) comparing the level of the fructan biosynthetic enzyme (fructosyltransferase) polypeptide or enzyme activity in the host cell containing the isolated polynucleotide or the isolated recombinant DNA construct with the level of the fructan biosynthetic enzyme (fructosyltransferase) polypeptide or enzyme activity in the host cell that does not contain the isolated polynucleotide or the isolated recombinant DNA construct.

In a fourteenth embodiment, the invention concerns a method of obtaining a nucleic acid fragment encoding a substantial portion of a fructan biosynthetic enzyme (fructosyltransferase) polypeptide, preferably a plant fructan biosynthetic enzyme (fructosyltransferase) polypeptide, comprising the steps of: synthesizing an oligonucleotide primer comprising a nucleotide sequence of at least one of 30 (preferably at least one of 40, most preferably at least one of 60) contiguous nucleotides derived from a nucleotide sequence selected from the group consisting of SEQ ID NOs:1, 3, 5, 7, 9, 11, 13, and 15 and the complement of such nucleotide sequences; and amplifying a nucleic acid fragment (preferably a cDNA inserted in a cloning vector) using the oligonucleotide primer. The amplified nucleic acid fragment preferably will encode a substantial portion of a fructan biosynthetic enzyme (fructosyltransferase) polypeptide amino acid sequence.

In a fifteenth embodiment, this invention relates to a method of obtaining a nucleic acid fragment encoding all or a substantial portion of the amino acid sequence encoding a fructan biosynthetic enzyme (fructosyltransferase) polypeptide comprising the steps of: probing a cDNA or genomic library with an isolated polynucleotide of the present invention; identifying a DNA clone that hybridizes with an isolated polynucleotide of the present invention; isolating the identified DNA clone; and sequencing the cDNA or genomic fragment that comprises the isolated DNA clone.

In a sixteenth embodiment, this invention concerns a composition, such as a hybridization mixture, comprising an isolated polynucleotide of the present invention.

In a seventeenth embodiment, this invention concerns a method for positive selection of a transformed cell comprising: (a) transforming a host cell with the recombinant DNA construct of the present invention or an expression cassette of the present invention; and (b) growing the transformed host cell, preferably a plant cell, such as a monocot or a dicot, under conditions which allow expression of the

fructan biosynthetic enzyme (fructosyltransferase) polypeptide in an amount sufficient to complement a null mutant to provide a positive selection means.

In an eighteenth embodiment, this invention relates to a method of altering the level of expression of a fructan biosynthetic enzyme (fructosyltransferase) polypeptide in a host cell comprising: (a) transforming a host cell with a recombinant DNA construct of the present invention; and (b) growing the transformed host cell under conditions that are suitable for expression of the recombinant DNA construct wherein expression of the recombinant DNA construct results in production of altered levels of the fructan biosynthetic enzyme (fructosyltransferase) polypeptide in the transformed host cell.

BRIEF DESCRIPTION OF THE DRAWINGS AND SEQUENCE LISTINGS

The invention can be more fully understood from the following detailed description and the accompanying drawings and Sequence Listing which form a part of this application.

Figures 1A-1C show an alignment of the 1-FFT amino acid sequences encoded by the African daisy clone dms2c.pk006.p1 (SEQ ID NO:2), the guayule clone epb3c.pk007.j9 (SEQ ID NO:4), and the sunflower clone hss1c.pk004.i5 (SEQ ID NO:6), with the *Helianthus tuberosus* 1-FFT (NCBI General Identifier No. 3367690; SEQ ID NO:17). Amino acids conserved among all sequences are indicated with an asterisk (*) above the alignment. The program uses dashes to maximize the alignment. Figure 1A shows amino acids 1 through 240, Figure 1B shows amino acids 241 through 480, and Figure 1C shows amino acids 481 through 624.

Figures 2A-2C shows an alignment of the 1-SST amino acid sequences encoded by the guayule clone epb3c.pk007.n11 (SEQ ID NO:14) and the sunflower clone hhs1c.pk004.e5 (SEQ ID NO:16), with the *Helianthus tuberosus* 1-SST (NCBI General Identifier No. 3367711; SEQ ID NO:18). Amino acids conserved among all sequences are indicated with an asterisk (*) above the alignment. The program uses dashes to maximize the alignment. Figure 2A shows amino acids 1 through 240, Figure 2B shows amino acids 241 through 480, and Figure 2C shows amino acids 481 through 625.

Figures 3A-3B show an alignment of the 6-SFT amino acid sequences encoded by the wheat clone wdk1c.pk014.c11 (SEQ ID NO:8), wheat clone wdk2c.pk017.f14 (SEQ ID NO:10), wheat clone wr1.pk0085.h8 (SEQ ID NO:12), and wheat clone wdk2c.pk017.f14:cgs (SEQ ID NO:20), with the *Hordeum vulgare* sequence (NCBI General Identifier No. 7435467; SEQ ID NO:21). Amino acids

conserved among all sequences are indicated with an asterisk (*) above the alignment. The program uses dashes to maximize the alignment. Figure 3A shows amino acids 1 through 350, and Figure 3B shows amino acids 351 through 637.

Table 1 lists the polypeptides that are described herein (including the plant source from where they are derived), the designation of the cDNA clones that comprise the nucleic acid fragments encoding polypeptides representing all or a substantial portion of these polypeptides, and the corresponding identifier (SEQ ID NO:) as used in the attached Sequence Listing. The table also includes the art sequences used in the figures, the polypeptide, source, and General Identifier No. (GI No.). The sequence descriptions and Sequence Listing attached hereto comply with the rules governing nucleotide and/or amino acid sequence disclosures in patent applications as set forth in 37 C.F.R. §1.821-1.825.

TABLE 1

The Sequence Listing contains the one letter code for nucleotide sequence characters and the three letter codes for amino acids as defined in conformity with the IUPAC-IUBMB standards described in *Nucleic Acids Res.* 13:3021-3030 (1985) and in the *Biochemical J.* 219 (No. 2):345-373 (1984) which are herein incorporated by reference. The symbols and format used for nucleotide and amino acid sequence data comply with the rules set forth in 37 C.F.R. §1.822.

DETAILED DESCRIPTION OF THE INVENTION

In the context of this disclosure, a number of terms shall be utilized. The terms "polynucleotide", "polynucleotide sequence", "nucleic acid sequence", and

“nucleic acid fragment”/“isolated nucleic acid fragment” are used interchangeably herein. These terms encompass nucleotide sequences and the like. A polynucleotide may be a polymer of RNA or DNA that is single- or double-stranded, that optionally contains synthetic, non-natural or altered nucleotide bases. A polynucleotide in the form of a polymer of DNA may be comprised of one or more segments of cDNA, genomic DNA, synthetic DNA, or mixtures thereof. An isolated polynucleotide of the present invention may include at least 30 contiguous nucleotides, preferably at least 40 contiguous nucleotides, most preferably at least 60 contiguous nucleotides derived from SEQ ID NOs:1, 3, 5, 13, 15, or 19 or the complement of such sequences.

The term “isolated” refers to materials, such as nucleic acid molecules and/or proteins, which are substantially free or otherwise removed from components that normally accompany or interact with the materials in a naturally occurring environment. Isolated polynucleotides may be purified from a host cell in which they naturally occur. Conventional nucleic acid purification methods known to skilled artisans may be used to obtain isolated polynucleotides. The term also embraces recombinant polynucleotides and chemically synthesized polynucleotides.

The term “recombinant” means, for example, that a nucleic acid sequence is made by an artificial combination of two otherwise separated segments of sequence, e.g., by chemical synthesis or by the manipulation of isolated nucleic acids by genetic engineering techniques.

As used herein, “substantially similar” refers to nucleic acid fragments wherein changes in one or more nucleotide bases results in substitution of one or more amino acids, but do not alter the functional properties of the polypeptide encoded by the nucleotide sequence. “Substantially similar” also refers to nucleic acid fragments wherein changes in one or more nucleotide bases does not change the ability of the nucleic acid fragment to mediate alteration of gene expression by gene silencing through for example antisense or co-suppression technology. “Substantially similar” also refers to modifications of the nucleic acid fragments of the instant invention such as deletion or insertion of one or more nucleotides that do not substantially affect the functional properties of the resulting transcript vis-à-vis the ability to mediate gene silencing or alteration of the functional properties of the resulting protein molecule. It is therefore understood that the invention encompasses more than the specific exemplary nucleotide or amino acid sequences and includes functional equivalents thereof. The terms “substantially similar” and “corresponding substantially” are used interchangeably herein.

Substantially similar nucleic acid fragments may be selected by screening nucleic acid fragments representing subfragments or modifications of the nucleic acid fragments of the instant invention, wherein one or more nucleotides are substituted, deleted and/or inserted, for their ability to affect the level of the polypeptide encoded by the unmodified nucleic acid fragment in a plant or plant cell. For example, a substantially similar nucleic acid fragment representing at least 30 contiguous nucleotides, preferably at least 40 contiguous nucleotides, most preferably at least 60 contiguous nucleotides derived from the instant nucleic acid fragment can be constructed and introduced into a plant or plant cell. The level of the polypeptide encoded by the unmodified nucleic acid fragment present in a plant or plant cell exposed to the substantially similar nucleic acid fragment can then be compared to the level of the polypeptide in a plant or plant cell that is not exposed to the substantially similar nucleic acid fragment.

For example, it is well known in the art that antisense suppression and co-suppression of gene expression may be accomplished using nucleic acid fragments representing less than the entire coding region of a gene, and by using nucleic acid fragments that do not share 100% sequence identity with the gene to be suppressed. Moreover, alterations in a nucleic acid fragment which result in the production of a chemically equivalent amino acid at a given site, but do not effect the functional properties of the encoded polypeptide, are well known in the art. Thus, a codon for the amino acid alanine, a hydrophobic amino acid, may be substituted by a codon encoding another less hydrophobic residue, such as glycine, or a more hydrophobic residue, such as valine, leucine, or isoleucine. Similarly, changes which result in substitution of one negatively charged residue for another, such as aspartic acid for glutamic acid, or one positively charged residue for another, such as lysine for arginine, can also be expected to produce a functionally equivalent product. Nucleotide changes which result in alteration of the N-terminal and C-terminal portions of the polypeptide molecule would also not be expected to alter the activity of the polypeptide. Each of the proposed modifications is well within the routine skill in the art, as is determination of retention of biological activity of the encoded products. Consequently, an isolated polynucleotide comprising a nucleotide sequence of at least 30 (preferably at least 40, most preferably at least 60) contiguous nucleotides derived from a nucleotide sequence selected from the group consisting of SEQ ID NOs:1, 3, 5, 13, or 15 and the complement of such nucleotide sequences may be used to affect the expression and/or function of a fructosyltransferase selected from 1-FFT, 6-SFT and 1-SST in a host cell. A method of using an isolated polynucleotide to affect the level of expression of a

polypeptide in a host cell (eukaryotic, such as plant or yeast, prokaryotic such as bacterial) may comprise the steps of: constructing an isolated polynucleotide of the present invention or an isolated chimeric gene of the present invention; introducing the isolated polynucleotide or the isolated chimeric gene into a host cell; measuring the level of a polypeptide or enzyme activity in the host cell containing the isolated polynucleotide; and comparing the level of a polypeptide or enzyme activity in the host cell containing the isolated polynucleotide with the level of a polypeptide or enzyme activity in a host cell that does not contain the isolated polynucleotide.

Moreover, substantially similar nucleic acid fragments may also be characterized by their ability to hybridize. Estimates of such homology are provided by either DNA-DNA or DNA-RNA hybridization under conditions of stringency as is well understood by those skilled in the art (Hames and Higgins, Eds. (1985) Nucleic Acid Hybridisation, IRL Press, Oxford, U.K.). Stringency conditions can be adjusted to screen for moderately similar fragments, such as homologous sequences from distantly related organisms, to highly similar fragments, such as genes that duplicate functional enzymes from closely related organisms. Post-hybridization washes determine stringency conditions. One set of preferred conditions uses a series of washes starting with 6X SSC, 0.5% SDS at room temperature for 15 min, then repeated with 2X SSC, 0.5% SDS at 45°C for 30 min, and then repeated twice with 0.2X SSC, 0.5% SDS at 50°C for 30 min. A more preferred set of stringent conditions uses higher temperatures in which the washes are identical to those above except for the temperature of the final two 30 min washes in 0.2X SSC, 0.5% SDS was increased to 60°C. Another preferred set of highly stringent conditions uses two final washes in 0.1X SSC, 0.1% SDS at 65°C.

Substantially similar nucleic acid fragments of the instant invention may also be characterized by the percent identity of the amino acid sequences that they encode to the amino acid sequences disclosed herein, as determined by algorithms commonly employed by those skilled in this art. Suitable nucleic acid fragments (isolated polynucleotides of the present invention) encode polypeptides that are at least about 70% identical, preferably at least about 80% identical to the amino acid sequences reported herein. Preferred nucleic acid fragments encode amino acid sequences that are at least about 85% identical to the amino acid sequences reported herein. More preferred nucleic acid fragments encode amino acid sequences that are at least about 90% identical to the amino acid sequences reported herein. Most preferred are nucleic acid fragments that encode amino acid sequences that are at least about 95% identical to the amino acid sequences reported herein. The amino acid sequences may be 96% identical, 97% identical,

98% identical, 99% identical, or any integer thereof. Suitable nucleic acid fragments not only have the above identities but typically encode a polypeptide having at least 50 amino acids, preferably at least 100 amino acids, more preferably at least 150 amino acids, still more preferably at least 200 amino acids, and most preferably at least 250 amino acids. Sequence alignments and percent identity calculations were performed using the Megalign program of the LASERGENE bioinformatics computing suite (DNASTAR Inc., Madison, WI). Multiple alignment of the sequences was performed using the Clustal method of alignment (Higgins and Sharp (1989) *CABIOS*. 5:151-153) with the default parameters (GAP PENALTY=10, GAP LENGTH PENALTY=10). Default parameters for pairwise alignments using the Clustal method were KTUPLE 1, GAP PENALTY=3, WINDOW=5 and DIAGONALS SAVED=5.

A "substantial portion" of an amino acid or nucleotide sequence comprises an amino acid or a nucleotide sequence that is sufficient to afford putative identification of the protein or gene that the amino acid or nucleotide sequence comprises. Amino acid and nucleotide sequences can be evaluated either manually by one skilled in the art, or by using computer-based sequence comparison and identification tools that employ algorithms such as BLAST (Basic Local Alignment Search Tool; Altschul et al. (1993) *J. Mol. Biol.* 215:403-410; see also the explanation of the BLAST algorithm on the world wide web site for the National Center for Biotechnology Information at the National Library of Medicine of the National Institutes of Health). In general, a sequence of ten or more contiguous amino acids or thirty or more contiguous nucleotides is necessary in order to putatively identify a polypeptide or nucleic acid sequence as homologous to a known protein or gene. Moreover, with respect to nucleotide sequences, gene-specific oligonucleotide probes comprising 30 or more contiguous nucleotides may be used in sequence-dependent methods of gene identification (e.g., Southern hybridization) and isolation (e.g., *in situ* hybridization of bacterial colonies or bacteriophage plaques). In addition, short oligonucleotides of 12 or more nucleotides may be used as amplification primers in PCR in order to obtain a particular nucleic acid fragment comprising the primers. Accordingly, a "substantial portion" of a nucleotide sequence comprises a nucleotide sequence that will afford specific identification and/or isolation of a nucleic acid fragment comprising the sequence. The instant specification teaches amino acid and nucleotide sequences encoding polypeptides that comprise one or more particular plant proteins. The skilled artisan, having the benefit of the sequences as reported herein, may now use all or a substantial portion of the disclosed sequences for purposes known to

those skilled in this art. Accordingly, the instant invention comprises the complete sequences as reported in the accompanying Sequence Listing, as well as substantial portions of those sequences as defined above.

“Codon degeneracy” refers to divergence in the genetic code permitting variation of the nucleotide sequence without effecting the amino acid sequence of an encoded polypeptide. Accordingly, the instant invention relates to any nucleic acid fragment comprising a nucleotide sequence that encodes all or a substantial portion of the amino acid sequences set forth herein. The skilled artisan is well aware of the “codon-bias” exhibited by a specific host cell in usage of nucleotide codons to specify a given amino acid. Therefore, when synthesizing a nucleic acid fragment for improved expression in a host cell, it is desirable to design the nucleic acid fragment such that its frequency of codon usage approaches the frequency of preferred codon usage of the host cell.

“Synthetic nucleic acid fragments” can be assembled from oligonucleotide building blocks that are chemically synthesized using procedures known to those skilled in the art. These building blocks are ligated and annealed to form larger nucleic acid fragments which may then be enzymatically assembled to construct the entire desired nucleic acid fragment. “Chemically synthesized”, as related to a nucleic acid fragment, means that the component nucleotides were assembled *in vitro*. Manual chemical synthesis of nucleic acid fragments may be accomplished using well established procedures, or automated chemical synthesis can be performed using one of a number of commercially available machines. Accordingly, the nucleic acid fragments can be tailored for optimal gene expression based on optimization of the nucleotide sequence to reflect the codon bias of the host cell. The skilled artisan appreciates the likelihood of successful gene expression if codon usage is biased towards those codons favored by the host. Determination of preferred codons can be based on a survey of genes derived from the host cell where sequence information is available.

“Gene” refers to a nucleic acid fragment that expresses a specific protein, including regulatory sequences preceding (5' non-coding sequences) and following (3' non-coding sequences) the coding sequence. “Native gene” refers to a gene as found in nature with its own regulatory sequences. “Chimeric gene” refers any gene that is not a native gene, comprising regulatory and coding sequences that are not found together in nature. Accordingly, a chimeric gene may comprise regulatory sequences and coding sequences that are derived from different sources, or regulatory sequences and coding sequences derived from the same source, but arranged in a manner different than that found in nature. “Endogenous gene” refers

to a native gene in its natural location in the genome of an organism. A "foreign-gene" refers to a gene not normally found in the host organism, but that is introduced into the host organism by gene transfer. Foreign genes can comprise native genes inserted into a non-native organism, or chimeric genes. A "transgene" is a gene that has been introduced into the genome by a transformation procedure.

"Coding sequence" refers to a nucleotide sequence that codes for a specific amino acid sequence. "Regulatory sequences" refer to nucleotide sequences located upstream (5' non-coding sequences), within, or downstream (3' non-coding sequences) of a coding sequence, and which influence the transcription, RNA processing or stability, or translation of the associated coding sequence. Regulatory sequences may include promoters, translation leader sequences, introns, and polyadenylation recognition sequences.

"Promoter" refers to a nucleotide sequence capable of controlling the expression of a coding sequence or functional RNA. In general, a coding sequence is located 3' to a promoter sequence. The promoter sequence consists of proximal and more distal upstream elements, the latter elements often referred to as enhancers. Accordingly, an "enhancer" is a nucleotide sequence which can stimulate promoter activity and may be an innate element of the promoter or a heterologous element inserted to enhance the level or tissue-specificity of a promoter. Promoters may be derived in their entirety from a native gene, or may be composed of different elements derived from different promoters found in nature, or may even comprise synthetic nucleotide segments. It is understood by those skilled in the art that different promoters may direct the expression of a gene in different tissues or cell types, or at different stages of development, or in response to different environmental conditions. Promoters which cause a nucleic acid fragment to be expressed in most cell types at most times are commonly referred to as "constitutive promoters". New promoters of various types useful in plant cells are constantly being discovered; numerous examples may be found in the compilation by Okamuro and Goldberg (1989) *Biochemistry of Plants* 15:1-82. It is further recognized that because in most cases the exact boundaries of regulatory sequences have not been completely defined, nucleic acid fragments of different lengths may have identical promoter activity.

"Translation leader sequence" refers to a nucleotide sequence located between the promoter sequence of a gene and the coding sequence. The translation leader sequence is present in the fully processed mRNA upstream of the translation start sequence. The translation leader sequence may affect processing of the primary transcript to mRNA, mRNA stability or translation efficiency.

Examples of translation leader sequences have been described (Turner and Foster (1995) *Mol. Biotechnol.* 3:225-236).

"3' non-coding sequences" refer to nucleotide sequences located downstream of a coding sequence and include polyadenylation recognition sequences and other sequences encoding regulatory signals capable of affecting mRNA processing or gene expression. The polyadenylation signal is usually characterized by effecting the addition of polyadenylic acid tracts to the 3' end of the mRNA precursor. The use of different 3' non-coding sequences is exemplified by Ingelbrecht et al. (1989) *Plant Cell* 1:671-680.

"RNA transcript" refers to the product resulting from RNA polymerase-catalyzed transcription of a DNA sequence. When the RNA transcript is a perfect complementary copy of the DNA sequence, it is referred to as the primary transcript or it may be a RNA sequence derived from posttranscriptional processing of the primary transcript and is referred to as the mature RNA. "Messenger RNA (mRNA)" refers to the RNA that is without introns and that can be translated into polypeptides by the cell. "cDNA" refers to DNA that is complementary to and derived from an mRNA template. The cDNA can be single-stranded or converted to double stranded form using, for example, the Klenow fragment of DNA polymerase I. "Sense-RNA" refers to an RNA transcript that includes the mRNA and so can be translated into a polypeptide by the cell. "Antisense RNA" refers to an RNA transcript that is complementary to all or part of a target primary transcript or mRNA and that blocks the expression of a target gene (see U.S. Patent No. 5,107,065, incorporated herein by reference). The complementarity of an antisense RNA may be with any part of the specific nucleotide sequence, i.e., at the 5' non-coding sequence, 3' non-coding sequence, introns, or the coding sequence. "Functional RNA" refers to sense RNA, antisense RNA, ribozyme RNA, or other RNA that may not be translated but yet has an effect on cellular processes.

The term "operably linked" refers to the association of two or more nucleic acid fragments on a single polynucleotide so that the function of one is affected by the other. For example, a promoter is operably linked with a coding sequence when it is capable of affecting the expression of that coding sequence (i.e., that the coding sequence is under the transcriptional control of the promoter). Coding sequences can be operably linked to regulatory sequences in sense or antisense orientation.

The term "expression", as used herein, refers to the transcription and stable accumulation of sense (mRNA) or antisense RNA derived from the nucleic acid fragment of the invention. Expression may also refer to translation of mRNA into a polypeptide. "Antisense inhibition" refers to the production of antisense RNA

transcripts capable of suppressing the expression of the target protein.

“Overexpression” refers to the production of a gene product in transgenic organisms that exceeds levels of production in normal or non-transformed organisms.

“Co-suppression” refers to the production of sense RNA transcripts capable of suppressing the expression of identical or substantially similar foreign or endogenous genes (U.S. Patent No. 5,231,020, incorporated herein by reference).

A “protein” or “polypeptide” is a chain of amino acids arranged in a specific order determined by the coding sequence in a polynucleotide encoding the polypeptide. Each protein or polypeptide has a unique function.

“Altered levels” or “altered expression” refers to the production of gene product(s) in transgenic organisms in amounts or proportions that differ from that of normal or non-transformed organisms.

“Mature protein” or the term “mature” when used in describing a protein refers to a post-translationally processed polypeptide; i.e., one from which any pre- or propeptides present in the primary translation product have been removed. “Precursor protein” or the term “precursor” when used in describing a protein refers to the primary product of translation of mRNA; i.e., with pre- and propeptides still present. Pre- and propeptides may be but are not limited to intracellular localization signals.

A “chloroplast transit peptide” is an amino acid sequence which is translated in conjunction with a protein and directs the protein to the chloroplast or other plastid types present in the cell in which the protein is made. “Chloroplast transit sequence” refers to a nucleotide sequence that encodes a chloroplast transit peptide. A “signal peptide” is an amino acid sequence which is translated in conjunction with a protein and directs the protein to the secretory system (Chrispeels (1991) *Ann. Rev. Plant Phys. Plant Mol. Biol.* 42:21-53). If the protein is to be directed to a vacuole, a vacuolar targeting signal (*supra*) can further be added, or if to the endoplasmic reticulum, an endoplasmic reticulum retention signal (*supra*) may be added. If the protein is to be directed to the nucleus, any signal peptide present should be removed and instead a nuclear localization signal included (Raikhel (1992) *Plant Phys.* 100:1627-1632).

“Transformation” refers to the transfer of a nucleic acid fragment into the genome of a host organism, resulting in genetically stable inheritance. Host organisms containing the transformed nucleic acid fragments are referred to as “transgenic” organisms. Examples of methods of plant transformation include *Agrobacterium*-mediated transformation (De Blaere et al. (1987) *Meth. Enzymoi.* 143:277) and particle-accelerated or “gene gun” transformation technology (Klein et

al. (1987) *Nature (London)* 327:70-73; U.S. Patent No. 4,945,050, incorporated herein by reference). Thus, isolated polynucleotides of the present invention can be incorporated into recombinant constructs, typically DNA constructs, capable of introduction into and replication in a host cell. Such a construct can be a vector that includes a replication system and sequences that are capable of transcription and translation of a polypeptide-encoding sequence in a given host cell. A number of vectors suitable for stable transfection of plant cells or for the establishment of transgenic plants have been described in, e.g., Pouwels et al., *Cloning Vectors: A Laboratory Manual*, 1985, supp. 1987; Weissbach and Weissbach, *Methods for Plant Molecular Biology*, Academic Press, 1989; and Flevin et al., *Plant Molecular Biology Manual*, Kluwer Academic Publishers, 1990. Typically, plant expression vectors include, for example, one or more cloned plant genes under the transcriptional control of 5' and 3' regulatory sequences and a dominant selectable marker. Such plant expression vectors also can contain a promoter regulatory region (e.g., a regulatory region controlling inducible or constitutive, environmentally- or developmentally-regulated, or cell- or tissue-specific expression), a transcription initiation start site, a ribosome binding site, an RNA processing signal, a transcription termination site, and/or a polyadenylation signal.

Standard recombinant DNA and molecular cloning techniques used herein are well known in the art and are described more fully in Sambrook et al. *Molecular Cloning: A Laboratory Manual*; Cold Spring Harbor Laboratory Press: Cold Spring Harbor, 1989 (hereinafter "Maniatis").

"PCR" or "polymerase chain reaction" is well known by those skilled in the art as a technique used for the amplification of specific DNA segments (U.S. Patent Nos. 4,683,195 and 4,800,159).

The present invention concerns isolated polynucleotides comprising a nucleotide sequence encoding a polypeptide having fructosyltransferase activity wherein (a) the amino acid sequence of the polypeptide and the amino acid sequence of SEQ ID NO:2, 4, or 6 have at least 90% sequence identity; (b) the amino acid sequence of the polypeptide and the amino acid sequence of SEQ ID NO:14 or 16 have at least 97% identity. It is preferred that the identity in (a) be at least 95%. The present invention also relates to isolated polynucleotides comprising the complement of the nucleotide sequence, wherein the complement and the nucleotide sequence contain the same number of nucleotides and are 100% complementary. More specifically, the present invention concerns isolated polynucleotides encoding 1-FFT polypeptides having the sequence of SEQ ID NO:2, 4, or 6, or 1-SST polypeptides having the sequence of SEQ ID NO:14 or 16.

Nucleic acid fragments encoding at least a portion of several fructosyltransferases have been isolated and identified by comparison of random plant cDNA sequences to public databases containing nucleotide and protein sequences using the BLAST algorithms well known to those skilled in the art. The nucleic acid fragments of the instant invention may be used to isolate cDNAs and genes encoding homologous proteins from the same or other plant species. Isolation of homologous genes using sequence-dependent protocols is well known in the art. Examples of sequence-dependent protocols include, but are not limited to, methods of nucleic acid hybridization, and methods of DNA and RNA amplification as exemplified by various uses of nucleic acid amplification technologies (e.g., polymerase chain reaction, ligase chain reaction).

For example, genes encoding other 1-FFT, 6-SFT, or 1-SST, either as cDNAs or genomic DNAs, could be isolated directly by using all or a portion of the instant nucleic acid fragments as DNA hybridization probes to screen libraries from any desired plant employing methodology well known to those skilled in the art. Specific oligonucleotide probes based upon the instant nucleic acid sequences can be designed and synthesized by methods known in the art (Maniatis). Moreover, an entire sequence can be used directly to synthesize DNA probes by methods known to the skilled artisan such as random primer DNA labeling, nick translation, end-labeling techniques, or RNA probes using available *in vitro* transcription systems. In addition, specific primers can be designed and used to amplify a part or all of the instant sequences. The resulting amplification products can be labeled directly during amplification reactions or labeled after amplification reactions, and used as probes to isolate full length cDNA or genomic fragments under conditions of appropriate stringency.

In addition, two short segments of the instant nucleic acid fragments may be used in polymerase chain reaction protocols to amplify longer nucleic acid fragments encoding homologous genes from DNA or RNA. The polymerase chain reaction may also be performed on a library of cloned nucleic acid fragments wherein the sequence of one primer is derived from the instant nucleic acid fragments, and the sequence of the other primer takes advantage of the presence of the polyadenylic acid tracts to the 3' end of the mRNA precursor encoding plant genes. Alternatively, the second primer sequence may be based upon sequences derived from the cloning vector. For example, the skilled artisan can follow the RACE protocol (Frohman et al. (1988) *Proc. Natl. Acad. Sci. USA* 85:8998-9002) to generate cDNAs by using PCR to amplify copies of the region between a single point in the transcript and the 3' or 5' end. Primers oriented in the 3' and

5' directions can be designed from the instant sequences. Using commercially available 3' RACE or 5' RACE systems (BRL), specific 3' or 5' cDNA fragments can be isolated (Ohara et al. (1989) *Proc. Natl. Acad. Sci. USA* 86:5673-5677; Loh et al. (1989) *Science* 243:217-220). Products generated by the 3' and 5' RACE procedures can be combined to generate full-length cDNAs (Frohman and Martin (1989) *Techniques* 1:165). Consequently, a polynucleotide comprising a nucleotide sequence of at least 30 (preferably at least 40, most preferably at least 60) contiguous nucleotides derived from a nucleotide sequence selected from the group consisting of SEQ ID NOs:1, 3, 5, 13, or 15 and the complement of such nucleotide sequences may be used in such methods to obtain a nucleic acid fragment encoding a substantial portion of an amino acid sequence of a polypeptide.

Availability of the instant nucleotide and deduced amino acid sequences facilitates immunological screening of cDNA expression libraries. Synthetic peptides representing portions of the instant amino acid sequences may be synthesized. These peptides can be used to immunize animals to produce polyclonal or monoclonal antibodies with specificity for peptides or proteins comprising the amino acid sequences. These antibodies can be then be used to screen cDNA expression libraries to isolate full-length cDNA clones of interest (Lerner (1984) *Adv. Immunol.* 36:1-34; Maniatis).

In another embodiment, this invention concerns viruses and host cells comprising either the chimeric genes of the invention as described herein or an isolated polynucleotide of the invention as described herein. Examples of host cells which can be used to practice the invention include, but are not limited to, yeast, bacteria, and plants.

As was noted above, the nucleic acid fragments of the instant invention may be used to create transgenic plants in which the disclosed polypeptides are present at higher or lower levels than normal or in cell types or developmental stages in which they are not normally found. This would have the effect of altering the fructan profile in those cells. Nucleic acid fragments encoding the fructan biosynthetic enzymes (fructosyltransferases) disclosed herein may be used to generate transgenic plants that produce particular fructans. In particular, the ability to produce fructans of the desired size in large amounts in crops of agronomic importance, such as corn or soybean, will reduce fructan production costs.

US Patent No. 5,840,361 teaches the health benefits of baby food compositions comprising fructan-containing vegetables. These benefits are based on the role of fructan-containing foods in stimulating the production of beneficial intestinal microbes, such as the *Bifidobacterium* species. *Bifidobacteria* are thought

to promote health by their fermentation of sugars in the colon. This activity inhibits the development of putrefactive bacteria and provides resistance to infective gastroenteritis (Langhendries et al. (1995) *J Ped Gastroenterol Nutr* 21:177-181; Jason et al. (1984) *Pediatrics* 74(Suppl):702-727; Howie et al. (1990) *Br Med J* 300:11-16). Stimulating colonic bifidobacteria may also result in the enhancement of immune functions, the improvement of digestion and absorption of essential nutrients, and the synthesis of vitamins (Gibson et al. (1995) *J Nutr* 125:1401-1412). One approach to increasing the colonic bifidobacteria in humans is termed prebiotics. Prebiotics involves feeding of a nondigestible food ingredient, such as fructooligosaccharides, that beneficially affects the microflora by selectively stimulating the growth and/or activity of beneficial bacteria. Oral administration to humans of fructans such as oligofructose and inulin have been shown to increase the number of bifidobacteria in stools (Gibson et al. (1995) *Gastroenterol* 108:975-982). Consequently, fructans have been recommended as dietary supplements to adult humans (Modler et al. (1990) *Can Inst Food Sci Technol J* 23:29-41). The enzymes 1-SST and 1-FFT are involved in the biosynthesis of inulin and other fructans. The overexpression of 1-SST and 1-FFT in crop species such as corn, wheat, rice and soybean should facilitate the production of fructan-containing material with beneficial prebiotic properties.

Overexpression of the proteins of the instant invention may be accomplished by first constructing a chimeric gene in which the coding region is operably linked to a promoter capable of directing expression of a gene in the desired tissues at the desired stage of development. The chimeric gene may comprise promoter sequences and translation leader sequences derived from the same genes. 3' Non-coding sequences encoding transcription termination signals may also be provided. The instant chimeric gene may also comprise one or more introns in order to facilitate gene expression.

Plasmid vectors comprising the instant isolated polynucleotide (or chimeric gene) may be constructed. The choice of plasmid vector is dependent upon the method that will be used to transform host plants. The skilled artisan is well aware of the genetic elements that must be present on the plasmid vector in order to successfully transform, select and propagate host cells containing the chimeric gene. The skilled artisan will also recognize that different independent transformation events will result in different levels and patterns of expression (Jones et al. (1985) *EMBO J.* 4:2411-2418; De Almeida et al. (1989) *Mol. Gen. Genetics* 218:78-86), and thus that multiple events must be screened in order to obtain lines displaying the desired expression level and pattern. Such screening may be

accomplished by amplification of DNA or RNA, Southern analysis of DNA, Northern analysis of mRNA expression, Western analysis of protein expression, or phenotypic analysis.

For some applications it may be useful to direct the instant polypeptides to different cellular compartments, or to facilitate their secretion from the cell. It is thus envisioned that the recombinant DNA fragments described above may be further supplemented by directing the coding sequence to encode the instant polypeptides with appropriate intracellular targeting sequences such as transit sequences (Keegstra (1989) *Cell* 56:247-253), signal sequences or sequences encoding endoplasmic reticulum localization (Chrispeels (1991) *Ann. Rev. Plant Phys. Plant Mol. Biol.* 42:21-53), or nuclear localization signals (Raikhel (1992) *Plant Phys.* 100:1627-1632) with or without removing targeting sequences that are already present. While the references cited give examples of each of these, the list is not exhaustive and more targeting signals of use may be discovered in the future.

It may also be desirable to reduce or eliminate expression of genes encoding the instant polypeptides in plants for some applications. In order to accomplish this, a chimeric gene designed for co-suppression of the instant polypeptide can be constructed by linking a gene or gene fragment encoding that polypeptide to plant promoter sequences. Alternatively, a chimeric gene designed to express antisense RNA for all or part of the instant nucleic acid fragment can be constructed by linking the gene or gene fragment in reverse orientation to plant promoter sequences. Either the co-suppression or antisense chimeric genes could be introduced into plants via transformation wherein expression of the corresponding endogenous genes are reduced or eliminated.

Molecular genetic solutions to the generation of plants with altered gene expression have a decided advantage over more traditional plant breeding approaches. Changes in plant phenotypes can be produced by specifically inhibiting expression of one or more genes by antisense inhibition or cosuppression (U.S. Patent Nos. 5,190,931, 5,107,065 and 5,283,323). An antisense or cosuppression construct would act as a dominant negative regulator of gene activity. While conventional mutations can yield negative regulation of gene activity these effects are most likely recessive. The dominant negative regulation available with a transgenic approach may be advantageous from a breeding perspective. In addition, the ability to restrict the expression of a specific phenotype to the reproductive tissues of the plant by the use of tissue specific promoters may confer agronomic advantages relative to conventional mutations which may have an effect in all tissues in which a mutant gene is ordinarily expressed.

5 The person skilled in the art will know that special considerations are associated with the use of antisense or cosuppression technologies in order to reduce expression of particular genes. For example, the proper level of expression of sense or antisense genes may require the use of different chimeric genes utilizing different regulatory elements known to the skilled artisan. Once transgenic plants are obtained by one of the methods described above, it will be necessary to screen individual transgenics for those that most effectively display the desired phenotype. Accordingly, the skilled artisan will develop methods for screening large numbers of transformants. The nature of these screens will generally be chosen on practical grounds. For example, one can screen by looking for changes in gene expression by using antibodies specific for the protein encoded by the gene being suppressed, or one could establish assays that specifically measure enzyme activity. A preferred method will be one which allows large numbers of samples to be processed rapidly, since it will be expected that a large number of transformants will be negative for the desired phenotype.

10 In another embodiment, the present invention concerns a fructosyltransferase polypeptide, most preferably a 1-FFT polypeptide having an amino acid sequence that is at least 90% identical, based on the Clustal method of alignment, to a polypeptide selected from the group consisting of SEQ ID NOs:2, 4, and 6. The preferred fructosyltransferase polypeptide may be a 1-SST polypeptide having an amino acid sequence that is at least 97% identical, based on the Clustal method of alignment, to a polypeptide selected from the group consisting of SEQ ID NOs:14 and 16.

15 The instant polypeptides (or portions thereof) may be produced in heterologous host cells, particularly in the cells of microbial hosts, and can be used to prepare antibodies to these proteins by methods well known to those skilled in the art. The antibodies are useful for detecting the polypeptides of the instant invention *in situ* in cells or *in vitro* in cell extracts. Preferred heterologous host cells for production of the instant polypeptides are microbial hosts. Microbial expression systems and expression vectors containing regulatory sequences that direct high level expression of foreign proteins are well known to those skilled in the art. Any of these could be used to construct a chimeric gene for production of the instant polypeptides. This chimeric gene could then be introduced into appropriate microorganisms via transformation to provide high level expression of the encoded fructosyltransferase (1-FFT, 6-SFT, or 1-SST). An example of a vector for high level expression of the instant polypeptides in a bacterial host is provided (Example 8).

1 All or a substantial portion of the polynucleotides of the instant invention may
also be used as probes for genetically and physically mapping the genes that they
are a part of, and used as markers for traits linked to those genes. Such
information may be useful in plant breeding in order to develop lines with desired
5 phenotypes. For example, the instant nucleic acid fragments may be used as
restriction fragment length polymorphism (RFLP) markers. Southern blots
(Maniatis) of restriction-digested plant genomic DNA may be probed with the nucleic
acid fragments of the instant invention. The resulting banding patterns may then be
subjected to genetic analyses using computer programs such as MapMaker (Lander
10 et al. (1987) *Genomics* 1:174-181) in order to construct a genetic map. In addition,
the nucleic acid fragments of the instant invention may be used to probe Southern
blots containing restriction endonuclease-treated genomic DNAs of a set of
individuals representing parent and progeny of a defined genetic cross.
Segregation of the DNA polymorphisms is noted and used to calculate the position
15 of the instant nucleic acid sequence in the genetic map previously obtained using
this population (Botstein et al. (1980) *Am. J. Hum. Genet.* 32:314-331).

The production and use of plant gene-derived probes for use in genetic
mapping is described in Bernatzky and Tanksley (1986) *Plant Mol. Biol. Reporter*
4:37-41. Numerous publications describe genetic mapping of specific cDNA clones
20 using the methodology outlined above or variations thereof. For example, F2
intercross populations, backcross populations, randomly mated populations, near
isogenic lines, and other sets of individuals may be used for mapping. Such
methodologies are well known to those skilled in the art.

Nucleic acid probes derived from the instant nucleic acid sequences may
25 also be used for physical mapping (i.e., placement of sequences on physical maps;
see Hoheisel et al. In: *Nonmammalian Genomic Analysis: A Practical Guide*,
Academic press 1996, pp. 319-346, and references cited therein).

Nucleic acid probes derived from the instant nucleic acid sequences may be
used in direct fluorescence *in situ* hybridization (FISH) mapping (Trask (1991)
30 *Trends Genet.* 7:149-154). Although current methods of FISH mapping favor use of
large clones (several to several hundred KB; see Laan et al. (1995) *Genome Res.*
5:13-20), improvements in sensitivity may allow performance of FISH mapping
using shorter probes.

A variety of nucleic acid amplification-based methods of genetic and physical
35 mapping may be carried out using the instant nucleic acid sequences. Examples
include allele-specific amplification (Kazazian (1989) *J. Lab. Clin. Med.* 11:95-96),
polymorphism of PCR-amplified fragments (CAPS; Sheffield et al. (1993) *Genomics*

16:325-332), allele-specific ligation (Landegren et al. (1988) *Science* 241:1077-1080), nucleotide extension reactions (Sokolov (1990) *Nucleic Acid Res.* 18:3671), Radiation Hybrid Mapping (Walter et al. (1997) *Nat. Genet.* 7:22-28) and Happy Mapping (Dear and Cook (1989) *Nucleic Acid Res.* 17:6795-6807). For these methods, the sequence of a nucleic acid fragment is used to design and produce primer pairs for use in the amplification reaction or in primer extension reactions. The design of such primers is well known to those skilled in the art. In methods employing PCR-based genetic mapping, it may be necessary to identify DNA sequence differences between the parents of the mapping cross in the region corresponding to the instant nucleic acid sequence. This, however, is generally not necessary for mapping methods.

Loss of function mutant phenotypes may be identified for the instant cDNA clones either by targeted gene disruption protocols or by identifying specific mutants for these genes contained in a maize population carrying mutations in all possible genes (Ballinger and Benzer (1989) *Proc. Natl. Acad. Sci USA* 86:9402-9406; Koes et al. (1995) *Proc. Natl. Acad. Sci USA* 92:8149-8153; Bensen et al. (1995) *Plant Cell* 7:75-84). The latter approach may be accomplished in two ways. First, short segments of the instant nucleic acid fragments may be used in polymerase chain reaction protocols in conjunction with a mutation tag sequence primer on DNAs prepared from a population of plants in which Mutator transposons or some other mutation-causing DNA element has been introduced (see Bensen, *supra*). The amplification of a specific DNA fragment with these primers indicates the insertion of the mutation tag element in or near the plant gene encoding the instant polypeptides. Alternatively, the instant nucleic acid fragment may be used as a hybridization probe against PCR amplification products generated from the mutation population using the mutation tag sequence primer in conjunction with an arbitrary genomic site primer, such as that for a restriction enzyme site-anchored synthetic adaptor. With either method, a plant containing a mutation in the endogenous gene encoding the instant polypeptides can be identified and obtained. This mutant plant can then be used to determine or confirm the natural function of the instant polypeptides disclosed herein.

EXAMPLES

The present invention is further defined in the following Examples, in which parts and percentages are by weight and degrees are Celsius, unless otherwise stated. It should be understood that these Examples, while indicating preferred embodiments of the invention, are given by way of illustration only. From the above discussion and these Examples, one skilled in the art can ascertain the essential

characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions. Thus, various modifications of the invention in addition to those shown and described herein will be apparent to those skilled in the art from the foregoing description. Such modifications are also intended to fall within the scope of the appended claims.

The disclosure of each reference set forth herein is incorporated herein by reference in its entirety.

EXAMPLE 1

Composition of cDNA Libraries: Isolation and Sequencing of cDNA Clones

cDNA libraries representing mRNAs from various African daisy (*Dimorphotheca sinuata*), guayule (*Parthenium argentatum* Grey), sunflower (*Helianthus* sp.), and wheat (*Triticum aestivum*) tissues were prepared. The general characteristics of the libraries are indicated below.

TABLE 2

cDNA Libraries from African Daisy, Guayule, Sunflower, and Wheat

Library	Tissue	Clone
dms2c	African Daisy Developing Seed	dms2c.pk006.p1
epb3c	Guayule Stem Bark	epb3c.pk007.j9 epb3c.pk007.n11
hhs1c	Sunflower Head Tissue Infected With Sclerotinia	hhs1c.pk004.e5
hss1c	Sclerotinia-Infected Sunflower Plant	hss1c.pk004.i5
wdk1c	Wheat Developing Kernel, 3 Days After Anthesis	wdk1c.pk014.c11
wdk2c	Wheat Developing Kernel, 7 Days After Anthesis	wdk2c.pk017.f14 wdk2c.pk017.f14:cg5
wr1	Wheat Root From 7 Day Old Seedling	wr1.pk0085.h8

cDNA libraries may be prepared by any one of many methods available. For example, the cDNAs may be introduced into plasmid vectors by first preparing the cDNA libraries in Uni-ZAP™ XR vectors according to the manufacturer's protocol (Stratagene Cloning Systems, La Jolla, CA). The Uni-ZAP™ XR libraries are converted into plasmid libraries according to the protocol provided by Stratagene. Upon conversion, cDNA inserts will be contained in the plasmid vector pBluescript. In addition, the cDNAs may be introduced directly into precut Bluescript II SK(+) vectors (Stratagene) using T4 DNA ligase (New England Biolabs), followed by transfection into DH10B cells according to the manufacturer's protocol (GIBCO BRL Products). Once the cDNA inserts are in plasmid vectors, plasmid DNAs are prepared from randomly picked bacterial colonies containing recombinant

pBluescript plasmids, or the insert cDNA sequences are amplified via polymerase chain reaction using primers specific for vector sequences flanking the inserted cDNA sequences. Amplified insert DNAs or plasmid DNAs are sequenced in dye-primer sequencing reactions to generate partial cDNA sequences (expressed sequence tags or "ESTs"; see Adams et al., (1991) *Science* 252:1651-1656). The resulting ESTs are analyzed using a Perkin Elmer Model 377 fluorescent sequencer.

Full-insert sequence (FIS) data is generated utilizing a modified transposition protocol. Clones identified for FIS are recovered from archived glycerol stocks as single colonies, and plasmid DNAs are isolated via alkaline lysis. Isolated DNA templates are reacted with vector primed M13 forward and reverse oligonucleotides in a PCR-based sequencing reaction and loaded onto automated sequencers. Confirmation of clone identification is performed by sequence alignment to the original EST sequence from which the FIS request is made.

Confirmed templates are transposed via the Primer Island transposition kit (PE Applied Biosystems, Foster City, CA) which is based upon the *Saccharomyces cerevisiae* Ty1 transposable element (Devine and Boeke (1994) *Nucleic Acids Res.* 22:3765-3772). The *in vitro* transposition system places unique binding sites randomly throughout a population of large DNA molecules. The transposed DNA is then used to transform DH10B electro-competent cells (Gibco BRL/Life Technologies, Rockville, MD) via electroporation. The transposable element contains an additional selectable marker (named DHFR; Fling and Richards (1983) *Nucleic Acids Res.* 11:5147-5158), allowing for dual selection on agar plates of only those subclones containing the integrated transposon. Multiple subclones are randomly selected from each transposition reaction, plasmid DNAs are prepared via alkaline lysis, and templates are sequenced (ABI Prism dye-terminator ReadyReaction mix) outward from the transposition event site, utilizing unique primers specific to the binding sites within the transposon.

Sequence data is collected (ABI Prism Collections) and assembled using Phred/Phrap (P. Green, University of Washington, Seattle). Phrep/Phrap is a public domain software program which re-reads the ABI sequence data, re-calls the bases, assigns quality values, and writes the base calls and quality values into editable output files. The Phrap sequence assembly program uses these quality values to increase the accuracy of the assembled sequence contigs. Assemblies are viewed by the Consed sequence editor (D. Gordon, University of Washington, Seattle).

In some of the clones the cDNA fragment corresponds to a portion of the 3'-terminus of the gene and does not cover the entire open reading frame. In order

to obtain the upstream information one of two different protocols are used. The first of these methods results in the production of a fragment of DNA containing a portion of the desired gene sequence while the second method results in the production of a fragment containing the entire open reading frame. Both of these methods use two rounds of PCR amplification to obtain fragments from one or more libraries. The libraries some times are chosen based on previous knowledge that the specific gene should be found in a certain tissue and some times are randomly-chosen. Reactions to obtain the same gene may be performed on several libraries in parallel or on a pool of libraries. Library pools are normally prepared using from 3 to 5 different libraries and normalized to a uniform dilution. . In the first round of amplification both methods use a vector-specific (forward) primer corresponding to a portion of the vector located at the 5'-terminus of the clone coupled with a gene-specific (reverse) primer. The first method uses a sequence that is complementary to a portion of the already known gene sequence while the second method uses a gene-specific primer complementary to a portion of the 3'-untranslated region (also referred to as UTR). In the second round of amplification a nested set of primers is used for both methods. The resulting DNA fragment is ligated into a pBluescript vector using a commercial kit and following the manufacturer's protocol. This kit is selected from many available from several vendors including Invitrogen (Carlsbad, CA), Promega Biotech (Madison, WI), and Gibco-BRL (Gaithersburg, MD). The plasmid DNA is isolated by alkaline lysis method and submitted for sequencing and assembly using Phred/Phrap, as above.

EXAMPLE 2

Identification of cDNA Clones

cDNA clones encoding fructosyltransferases (1-FFT, 6-SFT, or 1-SST) were identified by conducting BLAST (Basic Local Alignment Search Tool; Altschul et al. (1993) *J. Mol. Biol.* 215:403-410; see also the explanation of the BLAST alogarithm on the world wide web site for the National Center for Biotechnology Information at the National Library of Medicine of the National Institutes of Health) searches for similarity to sequences contained in the BLAST "nr" database (comprising all non-redundant GenBank CDS translations, sequences derived from the 3-dimensional structure Brookhaven Protein Data Bank, the last major release of the SWISS-PROT protein sequence database, EMBL, and DDBJ databases). The cDNA sequences obtained in Example 1 were analyzed for similarity to all publicly available DNA sequences contained in the "nr" database using the BLASTN algorithm provided by the National Center for Biotechnology Information (NCBI). The DNA sequences were translated in all reading frames and compared for

similarity to all publicly available protein sequences contained in the "nr" database using the BLASTX algorithm (Gish and States (1993) *Nat. Genet.* 3:266-272) provided by the NCBI. For convenience, the P-value (probability) of observing a match of a cDNA sequence to a sequence contained in the searched databases merely by chance as calculated by BLAST are reported herein as "pLog" values, which represent the negative of the logarithm of the reported P-value. Accordingly, the greater the pLog value, the greater the likelihood that the cDNA sequence and the BLAST "hit" represent homologous proteins.

ESTs submitted for analysis are compared to the genbank database as described above. ESTs that contain sequences more 5- or 3-prime can be found by using the BLASTn algorithm (Altschul et al (1997) *Nucleic Acids Res.* 25:3389-3402.) against the Du Pont proprietary database comparing nucleotide sequences that share common or overlapping regions of sequence homology. Where common or overlapping sequences exist between two or more nucleic acid fragments, the sequences can be assembled into a single contiguous nucleotide sequence, thus extending the original fragment in either the 5 or 3 prime direction. Once the most 5-prime EST is identified, its complete sequence can be determined by Full Insert Sequencing as described in Example 1. Homologous genes belonging to different species can be found by comparing the amino acid sequence of a known gene (from either a proprietary source or a public database) against an EST database using the tBLASTn algorithm. The tBLASTn algorithm searches an amino acid query against a nucleotide database that is translated in all 6 reading frames. This search allows for differences in nucleotide codon usage between different species, and for codon degeneracy.

EXAMPLE 3

Characterization of cDNA Clones Encoding 1-FFT

The BLASTX search using the EST sequences from clones listed in Table 3 revealed similarity of the polypeptides encoded by the cDNAs to 1-FFT from *Helianthus tuberosus* (NCBI General Identifier No. 3367690). Shown in Table 3 are the BLAST results for individual ESTs ("EST"), or for the sequences of the entire cDNA inserts comprising the indicated cDNA clones ("FIS") and encoding the entire protein ("CGS"):

TABLE 3

BLAST Results for Sequences Encoding Polypeptides
Homologous to 1-FFT

Clone	Status	BLAST pLog Score NCBI GI No.3367690
dms2c.pk006.p1: fis	CGS	>180.00
epb3c.pk007.j9: fis	CGS	>180.00
hss1c.pk004.i5	EST	83.70

The nucleotide sequence of the entire cDNA insert in clone dms2c.pk006.p1 is shown in SEQ ID NO:1. The amino acid sequence deduced from nucleotides 33 through 1856 of SEQ ID NO:1 is shown in SEQ ID NO:2. The nucleotide sequence of the entire cDNA insert in clone epb3c.pk007.j9 is shown in SEQ ID NO:3. The amino acid sequence deduced from nucleotides 63 through 1889 of SEQ ID NO:3 is shown in SEQ ID NO:4. The nucleotide sequence of a portion of the cDNA insert in clone hss1c.pk004.i5 is shown in SEQ ID NO:5. The amino acid sequence deduced from nucleotides 1 through 413 of SEQ ID NO:5 is shown in SEQ ID NO:6.

Figures 1A-1C present an alignment of the amino acid sequences set forth in SEQ ID NOs:2, 4, and 6 with the *Helianthus tuberosus* 1-FFT sequence (NCBI General Identifier No. 3367690; SEQ ID NO:17). The alignment indicates with an asterisk (*) above the alignment the amino acids conserved among all the sequences. Figure 1A shows amino acids 1 through 240, Figure 1B shows amino acids 241 through 480, and Figure 1C shows amino acids 481 through 624.

According to van der Meer et al. ((1998) *Plant J.* 15:489-500) the *Helianthus tuberosus* amino acid sequence has a signal sequence corresponding to amino acids 1 through 80. It can be clearly seen from the alignment that the polypeptides having SEQ ID NO:2 and SEQ ID NO:4 contain the conserved domains highlighted by Cha et al. ((2001) *J. Biotech.* 91:49-61) and the conserved Asp and Glu suggested by Saito et al. ((1997) *Biosci. Biotech. Biochem.* 61:2076-2079) as playing a role as nucleophile and proton donor in the catalytic mechanism of fructosyltransferases. In 1-FFTs the "FRDP-F motif" is included within the conserved motif Phe-His-Phe-Gln-Pro-Ala-Lys-Asn-Phe-Ile-Asp-Pro-Xaa-Gly. The "ECPD-R motif" is included within the conserved domain His-Ser-Val-Pro-Asn-Thr-Asp-Met-Trp-Glu-Cys-Val-Asp-Phe-Tyr-Pro-Val-Ser-Leu-Thr-Asn-Asp-Ser-Ala-Leu-Asp. The putative active Asp is included in the first domain and is located at position 95 of both, SEQ ID NO:2 and SEQ ID NO:4. The conserved Glu is found in the second domain, at position 277 of both, SEQ ID NO:2 and SEQ ID NO:4.

The data in Table 4 presents the percent identity of the amino acid sequences set forth in SEQ ID NOs:2, 4, and 6 with the *Helianthus tuberosus* sequence (NCBI General Identifier No. 3367690; SEQ ID NO:17).

TABLE 4

Percent Identity of Amino Acid Sequences
Deduced From the Nucleotide Sequences
of cDNA Clones Encoding Polypeptides Homologous to 1-FFT

Clone	SEQ ID NO.	Percent Identity to 3367690
dms2c.pk006.p1: fis	2	79.5
epb3c.pk007.j9: fis	4	84.9
hss1c.pk004.i5	6	86.5

Sequence alignments and percent identity calculations were performed using the Megalign program of the LASERGENE bioinformatics computing suite (DNASTAR Inc., Madison, WI). Multiple alignment of the sequences was performed using the Clustal method of alignment (Higgins and Sharp (1989) *CABIOS*.

5:151-153) with the default parameters (GAP PENALTY=10, GAP LENGTH PENALTY=10). Default parameters for pairwise alignments using the Clustal method were KTUPLE 1, GAP PENALTY=3, WINDOW=5 and DIAGONALS SAVED=5. Sequence alignments and BLAST scores and probabilities indicate that the nucleic acid fragments comprising the instant cDNA clones encode entire African daisy and Guayule 1-FFT and a substantial portion of a sunflower 1-FFT.

These sequences represent the first African daisy, guayule, and sunflower sequences encoding 1-FFT known to Applicant.

EXAMPLE 4

Characterization of cDNA Clones Encoding 6-SFT

The BLASTX search using the EST sequences from clones listed in Table 3 revealed similarity of the polypeptides encoded by the cDNAs to 6-SFT from *Hordeum vulgare* (NCBI General Identifier No. 7435467). Shown in Table 5 are the BLAST results for the sequences of the entire cDNA inserts comprising the indicated cDNA clones ("FIS"):

TABLE 5
BLAST Results for Sequences Encoding Polypeptides
Homologous to 6-SFT

Clone	Status	BLAST pLog Score 7435467
wdk1c.pk014.c11	FIS	>180.00
wdk2c.pk017.f14	FIS	>180.00
wr1.pk0085.h8	FIS	21.30

The nucleotide sequence of the entire cDNA insert in clone wdk1c.pk014.c11 is shown in SEQ ID NO:7. The amino acid sequence deduced from nucleotides 3 through 1487 of SEQ ID NO:7 is shown in SEQ ID NO:8. The nucleotide sequence of the entire cDNA insert in clone wdk2c.pk017.f14 is shown in SEQ ID NO:9. The amino acid sequence deduced from nucleotides 1 through 1413 of SEQ ID NO:9 is shown in SEQ ID NO:10. The nucleotide sequence of the entire cDNA insert in clone wr1.pk0085.h8 is shown in SEQ ID NO:11. The amino acid sequence deduced from nucleotides 1 through 174 of SEQ ID NO:11 is shown in SEQ ID NO:12.

The nucleotide sequence encoding the N-terminus for the polypeptide encoded by the cDNA insert in clone wdk2c.pk017.f14 was obtained. The BLASTP search using the amino acid sequence from clones wdk2c.pk017.f14 revealed similarity of the 6-SFT polypeptide from *Hordeum vulgare* (NCBI General Identifier No. 7435467). Shown in Table 6 are the BLAST results for the amino acid sequence of the entire protein encoded by the indicated clone (CGS):

TABLE 6
BLAST Results for Sequences Encoding Polypeptides
Homologous to 6-SFT

Clone	Status	BLAST pLog Score 7435467
wdk2c.pk017.f14:cgs	CGS	>180.00

A contig of the nucleotide sequence of the entire cDNA insert in clone wdk2c.pk017.f14 and 5'PCR is shown in SEQ ID NO:19. The amino acid sequence deduced from nucleotides 3 through 1916 of SEQ ID NO:19 is shown in SEQ ID NO:20.

Figures 3A-3B present an alignment of the amino acid sequences set forth in SEQ ID NOs:8, 10, 12, and 20 with the *Hordeum vulgare* sequence (NCBI General Identifier No. 7435467; SEQ ID NO:21). The alignment indicates with an asterisk (*)

above the alignment the amino acids conserved among all the sequences. Dashes are used by the program to maximize the alignment. Figure 3A shows amino acids 1 through 350, and Figure 3B shows amino acids 351 through 637. It can be clearly seen from the alignment that the polypeptide having SEQ ID NO:20 contains both of the conserved domains mentioned in Example 3 and that SEQ ID NO:8, 10, and 12 only contain the second motif. In 6-SFTs the "FRDP-F motif" is contained within the conserved domain Gln-Thr-Ala-Lys-Asn-Tyr-Met-Ser-Asp-Pro-Asn-Gly-Leu-Met-Tyr which includes the "active Asp" at position 77 of SEQ ID NO:20. In 6-SFTs the "ECPD-R motif" is included within the domain Arg-Thr-Gly-Glu-Trp-Glu-Cys-Ile-Asp-Phe-Tyr-Pro-Val-Gly. The "active Glu" is found at position 158 of SEQ ID NO:8, at position 134 of SEQ ID NO:10, and at position 263 of SEQ ID NO:20.

The data in Table 7 presents the percent identity of the amino acid sequences set forth in SEQ ID NOs:8, 10, 12, and 20 with the *Hordeum vulgare* sequence (NCBI General Identifier No. 7435467; SEQ ID NO:21).

TABLE 7
Percent Identity of Amino Acid Sequences
Deduced From the Nucleotide Sequences of cDNA Clones
Encoding Polypeptides Homologous to 6-SFT

Clone	SEQ ID NO.	Percent Identity to 7435467
wdk1c.pk014.c11	8	94.9
wdk2c.pk017.f14	10	94.7
wr1.pk0085.h8	12	84.5
wdk2c.pk017.f14:cgs	20	88.7

Sequence alignments and percent identity calculations were performed using the Megalign program of the LASERGENE bioinformatics computing suite (DNASTAR Inc., Madison, WI). Multiple alignment of the sequences was performed using the Clustal method of alignment (Higgins and Sharp (1989) *CABIOS* 5:151-153) with the default parameters (GAP PENALTY=10, GAP LENGTH PENALTY=10). Default parameters for pairwise alignments using the Clustal method were KTUPLE 1, GAP PENALTY=3, WINDOW=5 and DIAGONALS SAVED=5. Sequence alignments and BLAST scores and probabilities indicate that the nucleic acid fragments comprising the instant cDNA clones encode an entire wheat 6-SFTs and substantial portions of a three wheat 6-SFTs. These sequences represent the first wheat sequences encoding 6-SFT known to Applicant.

EXAMPLE 5

Characterization of cDNA Clones Encoding 1-SST

The BLASTX search using the EST sequences from clones listed in Table 8 revealed similarity of the polypeptides encoded by the cDNAs to 1-SST from *Helianthus tuberosus* (NCBI General Identifier No. 3367711). Shown in Table 7 are the BLAST results for the sequences of the entire cDNA inserts comprising the indicated cDNA clones ("FIS") encoding an entire protein ("CGS"):

TABLE 8

BLAST Results for Sequences Encoding
Polypeptides Homologous to 1-SST

Clone	Status	BLAST pLog Score NCBI GI No. 3367711
epb3c.pk007.n11	CGS	>180.00
hhs1c.pk004.e5	CGS	>180.00

The nucleotide sequence of the entire cDNA insert in clone epb3c.pk007.n11 is shown in SEQ ID NO:13. The amino acid sequence deduced from nucleotides 42 through 1946 of SEQ ID NO:13 is shown in SEQ ID NO:14. The nucleotide sequence of the entire cDNA insert in clone hhs1c.pk004.e5 is shown in SEQ ID NO:15. The amino acid sequence deduced from nucleotides 59 through 1890 of SEQ ID NO:15 is shown in SEQ ID NO:16.

Figures 2A-2C present an alignment of the amino acid sequences set forth in SEQ ID NOs:14 and 16 with the *Helianthus tuberosus* 1-SST sequence (NCBI General Identifier No. 3367711; SEQ ID NO:18). The alignment indicates with an asterisk (*) above the alignment the amino acids conserved among all the sequences. According to van der Meer et al. ((1998) *Plant J.* 15:489-500) the mature *Helianthus* peptide consists of amino acids 100 through 630. Figure 2A shows amino acids 1 through 240, Figure 2B shows amino acids 241 through 480, and Figure 2C shows amino acids 481 through 625.

It can be clearly seen from the alignment that the polypeptides having SEQ ID NO:14 and SEQ ID NO:16 contain conserved domains which include the motifs mentioned in Example 3. In 1-SSTs the "FRDP-F motif" is contained within the conserved domain Tyr-His-Phe-Gln-Pro-Asp-Lys-Xaa-Ile-Ser-Asp-Pro-Asp-Gly-Pro-Met-Tys-His which includes the "active Asp" at position 115 of SEQ ID NO:14 and at position 108 of SEQ ID NO:16. In 1-SSTs the "ECPD-R motif" is included within the domain Glu-Glu-Val-Leu-His-Ala-Val-Pro-His-Thr-Gly-Met-Trp-Asp-Cys-Val-

Asp-Leu-tyr-Pro. The "active Glu" is found at position 293 of SEQ ID NO:8 and at position 286 of SEQ ID NO:20.

The data in Table 9 presents the percent identity of the amino acid sequences set forth in SEQ ID NOs:14 and 16 with the *Helianthus tuberosus* sequence (NCBI General Identifier No. 3367711; SEQ ID NO:18).

TABLE 9
Percent Identity of Amino Acid Sequences
Deduced From the Nucleotide Sequences of cDNA Clones
Encoding Polypeptides Homologous to 1-SST

Clone	SEQ ID NO.	Percent Identity to 3367711
epb3c.pk007.n11	14	89.2
hhs1c.pk004.e5	16	96.8

Sequence alignments and percent identity calculations were performed using the Megalign program of the LASERGENE bioinformatics computing suite (DNASTAR Inc., Madison, WI). Multiple alignment of the sequences was performed using the Clustal method of alignment (Higgins and Sharp (1989) CABIOS. 5:151-153) with the default parameters (GAP PENALTY=10, GAP LENGTH PENALTY=10). Default parameters for pairwise alignments using the Clustal method were KTUPLE 1, GAP PENALTY=3, WINDOW=5 and DIAGONALS SAVED=5. Sequence alignments and BLAST scores and probabilities indicate that the nucleic acid fragments comprising the instant cDNA clones encode entire 1-SSTs. These sequences represent the first sunflower and guayule sequences encoding 1-SST known to Applicant.

EXAMPLE 6

Expression of Chimeric Genes in Monocot Cells

A chimeric gene comprising a cDNA encoding the instant polypeptides in sense orientation with respect to the maize 27 kD zein promoter that is located 5' to the cDNA fragment, and the 10 kD zein 3' end that is located 3' to the cDNA fragment, can be constructed. The cDNA fragment of this gene may be generated by polymerase chain reaction (PCR) of the cDNA clone using appropriate oligonucleotide primers. Cloning sites (NcoI or SmaI) can be incorporated into the oligonucleotides to provide proper orientation of the DNA fragment when inserted into the digested vector pML103 as described below. Amplification is then performed in a standard PCR. The amplified DNA is then digested with restriction enzymes NcoI and SmaI and fractionated on an agarose gel. The appropriate band can be isolated from the gel and combined with a 4.9 kb NcoI-SmaI fragment of the

plasmid pML103. Plasmid pML103 has been deposited under the terms of the Budapest Treaty at ATCC (American Type Culture Collection, 10801 University Blvd., Manassas, VA 20110-2209), and bears accession number ATCC 97366. The DNA segment from pML103 contains a 1.05 kb Sall-NcoI promoter fragment of the maize 27 kD zein gene and a 0.96 kb SmaI-Sall fragment from the 3' end of the maize 10 kD zein gene in the vector pGem9Zf(+) (Promega). Vector and insert DNA can be ligated at 15°C overnight, essentially as described (Maniatis). The ligated DNA may then be used to transform *E. coli* XL1-Blue (Epicurian Coli XL-1 Blue™; Stratagene). Bacterial transformants can be screened by restriction enzyme digestion of plasmid DNA and limited nucleotide sequence analysis using the dideoxy chain termination method (Sequenase™ DNA Sequencing Kit; U.S. Biochemical). The resulting plasmid construct would comprise a chimeric gene encoding, in the 5' to 3' direction, the maize 27 kD zein promoter, a cDNA fragment encoding the instant polypeptides, and the 10 kD zein 3' region.

The chimeric gene described above can then be introduced into corn cells by the following procedure. Immature corn embryos can be dissected from developing caryopses derived from crosses of the inbred corn lines H99 and LH132. The embryos are isolated 10 to 11 days after pollination when they are 1.0 to 1.5 mm long. The embryos are then placed with the axis-side facing down and in contact with agarose-solidified N6 medium (Chu et al. (1975) *Sci. Sin. Peking* 18:659-668). The embryos are kept in the dark at 27°C. Friable embryogenic callus consisting of undifferentiated masses of cells with somatic proembryoids and embryoids borne on suspensor structures proliferates from the scutellum of these immature embryos. The embryogenic callus isolated from the primary explant can be cultured on N6 medium and sub-cultured on this medium every 2 to 3 weeks.

The plasmid, p35S/Ac (obtained from Dr. Peter Eckes, Hoechst Ag, Frankfurt, Germany) may be used in transformation experiments in order to provide for a selectable marker. This plasmid contains the *Pat* gene (see European Patent Publication 0 242 236) which encodes phosphinothricin acetyl transferase (PAT). The enzyme PAT confers resistance to herbicidal glutamine synthetase inhibitors such as phosphinothricin. The *pat* gene in p35S/Ac is under the control of the 35S promoter from Cauliflower Mosaic Virus (Odell et al. (1985) *Nature* 313:810-812) and the 3' region of the nopaline synthase gene from the T-DNA of the Ti plasmid of *Agrobacterium tumefaciens*.

The particle bombardment method (Klein et al. (1987) *Nature* 327:70-73) may be used to transfer genes to the callus culture cells. According to this method, gold particles (1 µm in diameter) are coated with DNA using the following technique.

Ten μg of plasmid DNAs are added to 50 μL of a suspension of gold particles (60 mg per mL). Calcium chloride (50 μL of a 2.5 M solution) and spermidine free base (20 μL of a 1.0 M solution) are added to the particles. The suspension is vortexed during the addition of these solutions. After 10 minutes, the tubes are briefly centrifuged (5 sec at 15,000 rpm) and the supernatant removed. The particles are resuspended in 200 μL of absolute ethanol, centrifuged again and the supernatant removed. The ethanol rinse is performed again and the particles resuspended in a final volume of 30 μL of ethanol. An aliquot (5 μL) of the DNA-coated gold particles can be placed in the center of a Kapton™ flying disc (Bio-Rad Labs). The particles are then accelerated into the corn tissue with a Biolistic™ PDS-1000/He (Bio-Rad Instruments, Hercules CA), using a helium pressure of 1000 psi, a gap distance of 0.5 cm and a flying distance of 1.0 cm.

For bombardment, the embryogenic tissue is placed on filter paper over agarose-solidified N6 medium. The tissue is arranged as a thin lawn and covered a circular area of about 5 cm in diameter. The petri dish containing the tissue can be placed in the chamber of the PDS-1000/He approximately 8 cm from the stopping screen. The air in the chamber is then evacuated to a vacuum of 28 inches of Hg. The macrocarrier is accelerated with a helium shock wave using a rupture membrane that bursts when the He pressure in the shock tube reaches 1000 psi.

Seven days after bombardment the tissue can be transferred to N6 medium that contains bialophos (5 mg per liter) and lacks casein or proline. The tissue continues to grow slowly on this medium. After an additional 2 weeks the tissue can be transferred to fresh N6 medium containing bialophos. After 6 weeks, areas of about 1 cm in diameter of actively growing callus can be identified on some of the plates containing the bialophos-supplemented medium. These calli may continue to grow when sub-cultured on the selective medium.

Plants can be regenerated from the transgenic callus by first transferring clusters of tissue to N6 medium supplemented with 0.2 mg per liter of 2,4-D. After two weeks the tissue can be transferred to regeneration medium (Fromm et al. (1990) *Bio/Technology* 8:833-839). Assays for fructosyltransferase activity may be conducted under well known experimental conditions which permit optimal enzymatic activity. For example, assays for 1-FFT and 1-SST are presented by van der Meer et al. (1998) *Plant J.* 15:489-500. Assays for 6-SFT are presented by Sprenger et al. (1995) *Proc. Natl. Acad. Sci. USA* 92:11652-11656.

EXAMPLE 7

Expression of Chimeric Genes in Dicot Cells

A seed-specific expression cassette composed of the promoter and transcription terminator from the gene encoding the β subunit of the seed storage protein phaseolin from the bean *Phaseolus vulgaris* (Doyle et al. (1986) *J. Biol. Chem.* 261:9228-9238) can be used for expression of the instant polypeptides in transformed soybean. The phaseolin cassette includes about 500 nucleotides upstream (5') from the translation initiation codon and about 1650 nucleotides downstream (3') from the translation stop codon of phaseolin. Between the 5' and 3' regions are the unique restriction endonuclease sites NcoI (which includes the ATG translation initiation codon), SmaI, KpnI and XbaI. The entire cassette is flanked by HindIII sites.

The cDNA fragment of this gene may be generated by polymerase chain reaction (PCR) of the cDNA clone using appropriate oligonucleotide primers. Cloning sites can be incorporated into the oligonucleotides to provide proper orientation of the DNA fragment when inserted into the expression vector. Amplification is then performed as described above, and the isolated fragment is inserted into a pUC18 vector carrying the seed expression cassette.

Soybean embryos may then be transformed with the expression vector comprising sequences encoding the instant polypeptides. To induce somatic embryos, cotyledons, 3-5 mm in length dissected from surface sterilized, immature seeds of the soybean cultivar A2872, can be cultured in the light or dark at 26°C on an appropriate agar medium for 6-10 weeks. Somatic embryos which produce secondary embryos are then excised and placed into a suitable liquid medium. After repeated selection for clusters of somatic embryos which multiplied as early, globular staged embryos, the suspensions are maintained as described below.

Soybean embryogenic suspension cultures can be maintained in 35 mL liquid media on a rotary shaker, 150 rpm, at 26°C with florescent lights on a 16:8 hour day/night schedule. Cultures are subcultured every two weeks by inoculating approximately 35 mg of tissue into 35 mL of liquid medium.

Soybean embryogenic suspension cultures may then be transformed by the method of particle gun bombardment (Klein et al. (1987) *Nature* (London) 327:70-73, U.S. Patent No. 4,945,050). A DuPont Biolistic™ PDS1000/HE instrument (helium retrofit) can be used for these transformations.

A selectable marker gene which can be used to facilitate soybean transformation is a chimeric gene composed of the 35S promoter from Cauliflower Mosaic Virus (Odell et al. (1985) *Nature* 313:810-812), the hygromycin

phosphotransferase gene from plasmid pJR225 (from *E. coli*; Gritz et al.(1983) *Gene* 25:179-188) and the 3' region of the nopaline synthase gene from the T-DNA of the Ti plasmid of *Agrobacterium tumefaciens*. The seed expression cassette comprising the phaseolin 5' region, the fragment encoding the instant polypeptides and the phaseolin 3' region can be isolated as a restriction fragment. This fragment can then be inserted into a unique restriction site of the vector carrying the marker gene.

To 50 μ L of a 60 mg/mL 1 μ m gold particle suspension is added (in order): 5 μ L DNA (1 μ g/ μ L), 20 μ L spermidine (0.1 M), and 50 μ L CaCl_2 (2.5 M). The particle preparation is then agitated for three minutes, spun in a microfuge for 10 seconds and the supernatant removed. The DNA-coated particles are then washed once in 400 μ L 70% ethanol and resuspended in 40 μ L of anhydrous ethanol. The DNA/particle suspension can be sonicated three times for one second each. Five μ L of the DNA-coated gold particles are then loaded on each macro carrier disk.

Approximately 300-400 mg of a two-week-old suspension culture is placed in an empty 60x15 mm petri dish and the residual liquid removed from the tissue with a pipette. For each transformation experiment, approximately 5-10 plates of tissue are normally bombarded. Membrane rupture pressure is set at 1100 psi and the chamber is evacuated to a vacuum of 28 inches mercury. The tissue is placed approximately 3.5 inches away from the retaining screen and bombarded three times. Following bombardment, the tissue can be divided in half and placed back into liquid and cultured as described above.

Five to seven days post bombardment, the liquid media may be exchanged with fresh media, and eleven to twelve days post bombardment with fresh media containing 50 mg/mL hygromycin. This selective media can be refreshed weekly. Seven to eight weeks post bombardment, green, transformed tissue may be observed growing from untransformed, necrotic embryogenic clusters. Isolated green tissue is removed and inoculated into individual flasks to generate new, clonally propagated, transformed embryogenic suspension cultures. Each new line may be treated as an independent transformation event. These suspensions can then be subcultured and maintained as clusters of immature embryos or regenerated into whole plants by maturation and germination of individual somatic embryos.

Assays for fructosyltransferase activity may be conducted under well known experimental conditions which permit optimal enzymatic activity. For example, assays for 1-FFT and 1-SST are presented by van der Meer et al. (1998) *Plant J.*

15:489-500. Assays for 6-SFT are presented by Sprenger et al. (1995) *Proc. Natl. Acad. Sci. USA* 92:11652-11656.

EXAMPLE 8

Expression of Chimeric Genes in Microbial Cells

5 The cDNAs encoding the instant polypeptides can be inserted into the T7
 E. coli expression vector pBT430. This vector is a derivative of pET-3a (Rosenberg
 et al. (1987) *Gene* 56:125-135) which employs the bacteriophage T7 RNA
 polymerase/T7 promoter system. Plasmid pBT430 was constructed by first
10 destroying the EcoRI and HindIII sites in pET-3a at their original positions. An
 oligonucleotide adaptor containing EcoRI and Hind III sites was inserted at the
 BamHI site of pET-3a. This created pET-3aM with additional unique cloning sites
 for insertion of genes into the expression vector. Then, the NdeI site at the position
 of translation initiation was converted to an NcoI site using oligonucleotide-directed
15 mutagenesis. The DNA sequence of pET-3aM in this region, 5'-CATATGG, was
 converted to 5'-CCCATGG in pBT430.

20 Plasmid DNA containing a cDNA may be appropriately digested to release a
 nucleic acid fragment encoding the protein. This fragment may then be purified on
 a 1% low melting agarose gel. Buffer and agarose contain 10 g/ml ethidium
 bromide for visualization of the DNA fragment. The fragment can then be purified
25 from the agarose gel by digestion with GELase™ (Epicentre Technologies, Madison,
 WI) according to the manufacturer's instructions, ethanol precipitated, dried and
 resuspended in 20 µL of water. Appropriate oligonucleotide adapters may be
 ligated to the fragment using T4 DNA ligase (New England Biolabs (NEB), Beverly,
30 MA). The fragment containing the ligated adapters can be purified from the excess
 adapters using low melting agarose as described above. The vector pBT430 is
 digested, dephosphorylated with alkaline phosphatase (NEB) and deproteinized
 with phenol/chloroform as described above. The prepared vector pBT430 and
 fragment can then be ligated at 16°C for 15 hours followed by transformation into
35 DH5 electrocompetent cells (GIBCO BRL). Transformants can be selected on agar
 plates containing LB media and 100 µg/mL ampicillin. Transformants containing the
 gene encoding the instant polypeptides are then screened for the correct orientation
 with respect to the T7 promoter by restriction enzyme analysis.

40 For high level expression, a plasmid clone with the cDNA insert in the correct
 orientation relative to the T7 promoter can be transformed into *E. coli* strain
45 BL21(DE3) (Studier et al. (1986) *J. Mol. Biol.* 189:113-130). Cultures are grown in
 LB medium containing ampicillin (100 mg/L) at 25°C. At an optical density at
 600 nm of approximately 1, IPTG (isopropylthio-β-galactoside, the inducer) can be

added to a final concentration of 0.4 mM and incubation can be continued for 3 h at 25°. Cells are then harvested by centrifugation and re-suspended in 50 µL of 50 mM Tris-HCl at pH 8.0 containing 0.1 mM DTT and 0.2 mM phenyl methylsulfonyl fluoride. A small amount of 1 mm glass beads can be added and the mixture sonicated 3 times for about 5 seconds each time with a microprobe sonicator. The mixture is centrifuged and the protein concentration of the supernatant determined. One µg of protein from the soluble fraction of the culture can be separated by SDS-polyacrylamide gel electrophoresis. Gels can be observed for protein bands migrating at the expected molecular weight.

Assays for fructosyltransferase activity may be conducted under well known experimental conditions which permit optimal enzymatic activity. For example, assays for 1-FFT and 1-SST are presented by van der Meer et al. (1998) *Plant J.* 15:489-500. Assays for 6-SFT are presented by Sprenger et al. (1995) *Proc. Natl. Acad. Sci.
